Kenai Peninsula Borough
144 North Binkley Street
Soldotna, Alaska 99669

Dear Mr. Mueller:

RE: Kenai Peninsula Borough Unit 395 Land Planning Soil Data Report

INTRODUCTION

RESPEC has evaluated the subsurface conditions across Unit 395 to support land planning efforts for this 1,080-acre parcel. Our evaluation consisted of excavating 40 machine excavated test pits across the parcel in areas accessible from the existing forest service road. In this report, we present the results of our geotechnical explorations, laboratory testing, and general planning level geotechnical recommendations.

All the test pits we excavated revealed conditions that would be generally suitable for residential development. Additionally, we identified one area (near test pits TP21-TP27) that has potential for development as a gravel borrow source.

SUBSURFACE EXPLORATIONS

We conducted subsurface explorations at the project site on September 19-21, 2022. Weather at the time of the explorations consisted of temperatures in the range of 60-75 °F with no precipitation. However, in the weeks prior to our exploration efforts, the region had experienced abnormally high amounts of precipitation. We subcontracted Quality Asphalt Paving (QAP) to provide an excavator and operator for the test pitting effort. QAP provided a Volvo EC201C4 excavator with a maximum excavation depth of approximately 20 feet and a maximum digging force of approximately 30,000 lbs. We excavated 40 test pits across the parcel to depths ranging from 2 feet (refusal on bedrock) to 16 feet below the ground surface (bgs). The approximate test pit locations are illustrated in Figure 1. Table 1 summarizes the location, excavated depth, and ground elevation of each test pit. Graphic test pit logs and photographs of the open test pits are attached to this report.

The initial approach to planning the locations of the test pits was to spread the test pits out relatively evenly along areas that could be easily accessed from the existing forest service road and then adjust locations in the field based on the materials encountered. Due to very wet muddy conditions on the forest service road in the southeast end of the parcel (locally referred to as Chunkwood Road), the test pits in this area were conducted by tracking the excavator through the woods and attempting to get a relatively even distribution of exploration locations. We used a GPS/GIS enabled Samsung Galaxy Tab A7 connected to a Trimble R1 GNSS receiver to navigate to and record the test pit locations.

TP40	1130	9.5	-149.92902	60.49560

LABORATORY TESTING

We collected a total of 31 soil samples from the 40 test pits and submitted the soil samples to RESPEC's materials testing laboratory in Juneau for further identification and geotechnical analysis. We tested the soil samples in general accordance with the respective ASTM standard tests methods including:

- / Moisture Content (ASTM D2216)
- / Particle Size Analysis of Soil (ASTM D422)

The laboratory test results, along with the observations we made during our subsurface exploration efforts, aid in our evaluations of the subsurface conditions. The results of the laboratory analyses are provided on laboratory test data sheets attached this report.

GENERAL SUBSURFACE CONDITIONS

Generally, the surficial organic layer was relatively thin in most of the test pits ranging from 0.5 to 2 feet thick. Only one test pit, TP5, encountered deeper organics at 3 feet thick. Beneath the surficial organics, the materials fluctuate between alluvium and colluvium which overlays either very dense glacial till or bedrock. In some areas, the near surface soils are moderately frost susceptible (refer to the attached laboratory results). The groundwater table was not encountered in any of the test pits but some minor seeps from perched water were observed as noted in the attached test pits logs. Where bedrock was encountered, it was generally fresh or slightly weathered.

As part of our evaluation, we also review subsurface data available from the DOT collected as part of the Cooper Landing Bypass Project. The DOT data revealed subsurface conditions similar to those we observed in our test pits. Based on the DOT data, the bedrock we encountered during our test pitting operations is likely slightly weathered to fresh schist.

ENGINEERING CONCLUSIONS

All the conditions observed in our test pitting effort are suitable for most forms of development, including residential development. The alluvium and colluvium are generally very dense to dense and should provide sufficient bearing capacity for building foundations (on the order of 2,000-3,000 psf with traditional design and construction techniques). The primary geotechnical concern will be the frost susceptibility of the near surface soils in some areas. This is a common challenge that can be easily overcome by avoiding unheated foundations, burying foundations below the frost line, utilizing insulated foundation designs, and replacing frost susceptible material with non-frost susceptible material.

With the limited amount of subsurface data collected from the test pits, the area surrounding test pits TP21-TP27 appears to have potential as a sand/gravel material source.

RECOMMENDATIONS

Any future developments should have project/site specific geotechnical evaluations conducted to support design efforts. This evaluation provides only planning level subsurface data and interpretation.

Prior to development of a material source near test pits TP21-27, more detailed geotechnical studies should be conducted with a drilling rig to evaluate the quantity and quality of the available materials. Drilling and sampling with a sonic rig is recommended for material source evaluation as this drilling method can collect relatively large samples more quickly than other traditional drilling techniques.

Should you have any questions regarding the data presented in this report, please reach out to me directly. It has been a pleasure assisting with this exciting project.

Sincerely,

Cody J. Kreitel, P.E.
Senior Geotechnical Engineer
